

Protolītiskā šķīdība ūdenī saista absolūtu elektrodu potenciālu ar absolūtās brīvās enerģijas skolas nulli  $G_{H_2O} = G_{CO_2\text{gas}} = 0 \text{ kJ/mol}$  un ir atkarīga no absolūtās temperatūras. Šķīdības un protolīzes reakcijās ar ūdens molekulām klasisko molāro koncentrāciju vietā termodinamikā ir jāizmanto ūdens, šķīstošo reaģēntu un produktu molu daļas.

Gāzu šķīdība: skābeklis  $O_2\text{gas} + H_2O = O_2\text{aq}$ ; ūdeņradis  $H_2\text{gas} + H_2O = H_2\text{aq}$ ; slāpeklis  $N_2\text{gas} + H_2O = N_2\text{aq}$ ; sērūdeņradis  $H_2S\text{gas} + H_2O = H_2S\text{aq}$ ; sēra dioksīds  $SO_2\text{gas} + H_2O = H_2SO_3\text{aq}$ ;

Metāla elektrodi: metāls ūdeņradis  $H(Pt) + H_2O = H_3O^+ + e^-$ ; dzelzs  $Fe_{(s)} + H_2O = Fe^{2+} + 2e^-$ ;

cinks  $Zn + H_2O = Zn^{2+} + 2e^-$ ; vara amalgama  $Cu(Hg) + H_2O = Cu^{2+} + (Hg) + 2e^-$ ; sudrabs  $Ag_{(s)} + H_2O = Ag^+ + e^-$ ; hroms  $Cr + H_2O = Cr^{3+} + 3e^-$ ;

Cietvielu šķīdība: sudraba hlorīds  $AgCl_{(s)} + 2H_2O = Ag^+ + Cl^-$ ; kalomels  $Hg_2Cl_{2(s)} + 3H_2O = Hg_2^{2+} + 2Cl^-$ ;

Protolīze: peroksīds  $H_2O_2 + H_2O = H_3O^+ + HO^-$   $pK_a = 11,75$ ; ūdens  $2H_2O = H_3O^+ + OH^-$   $pK_w = 14$ .

Gāzveida skābekļa šķīdība ūdenī  $O_2\text{gas} + H_2O = O_2\text{aq}$  kompensē vienu ūdens molekulu oksidēšanas pus reakcijā  $6H_2O = O_2\text{gas} + 4H_3O^+ + 4e^-$  no sešām uz piecām  $5H_2O = O_2\text{aq} + 4H_3O^+ + 4e^-$ . Tas samazina metāla ūdeņraža brīvās enerģijas nomērīto saturu no  $G_{H(Pt)} = 51,05 \text{ kJ/mol}$  uz  $G_{H(Pt)} = 48,56 \text{ kJ/mol}$ . Absolūtā potenciāla skolas atskaites vērtība palielinās no  $E^\circ_H = -0,29654 \text{ V}$  uz  $E^\circ_H = -0,27073 \text{ V}$  mazāk negatīva. Absolūtā potenciāla skolas izmaiņa no termodinamiskās  $0,10166 \text{ V}$  uz  $-0,37239 \text{ V}$  ir savienota summa  $\Delta E^\circ = +0,10166 - 0,37239$ .

Standarta potenciāls samazinās līdz vērtībai  $E^\circ_{O_2} = 1,0868 \text{ V}$  skābeklim un glikozei  $E^\circ_{C_6H_{12}O_6} = -0,13858 \text{ V}$ .

Darbību secība divu ūdens molekulu oksidēšanā par skābekli  $5H_2O = O_2\text{aq} + 4H_3O^+ + 4e^-$  absolūtā standarta potenciāla  $E^\circ_{O_2} = 1,0868 \text{ Volti}$  noteikšanai.

No Nernsta klasiskās vērtības  $E^\circ_{\text{classic}O_2} = 1,2288 \text{ V}$  atņem  $E^\circ_{H_2O} = -0,0591/4 * \log(1/55,3^5) = 0,1287 \text{ piecu ūdens molekulu logaritmisko vērtību}$ . Ūdens koncentrācija vienā litrā ir  $55,3 \text{ M}$ , ja šķīdumu summārās koncentrācijas ir mazākas par  $<0,1 \text{ M}$ . Tad pieskaita savienoto summu  $\Delta E^\circ = +0,10166 - 0,37239$ . Absolūtais standarta potenciāls tiek summēts no trim komponentiem klasiskais  $E^\circ_{\text{klasiskais}}$  ūdens logaritma uzskaitē  $+ \Delta E^\circ$ :

$$E^\circ_{O_2} = E^\circ_{\text{klasiskais}O_2} - 0,0591/4 * \log(1/55,3^5) + \Delta E^\circ = 1,2288 + 0,1287 + 0,10166 - 0,37239 = 1,0868 \text{ Volti.}$$

Tādējādi Nernsta pus reakcijai  $5H_2O = O_2\text{aq} + 4H_3O^+ + 4e^-$  iegūst absolūtā potenciāla izteiksmi vienādojumā:

$$E_{O_2} = E^\circ_{O_2} + 0,0591/4 * \log \frac{[O_2]_{\text{aqua}} \cdot [H_3O^+]^4}{[H_2O]^5} = 1,0868 + 0,0591/4 * \log \frac{[O_2]_{\text{aqua}} \cdot [H_3O^+]^4}{55,3^5} \text{ Volti.}$$

Skābekļa reducēšanas  $O_2\text{aq} + 4H_3O^+ + 4e^- \rightleftharpoons 5H_2O$  inversais standarta potenciāls ir ar mīnusa zīmi  $-E^\circ_{O_2}$ .

Skābekļa reducēšanas reakcija ir eksoergīska  $\Delta G_{eqO_2} = E^\circ_{O_2} \cdot F \cdot n = -1,0868 * 96485 * 4 / 1000 = -419,44 \text{ kJ/mol}$ ;  $\Delta G_{eqO_2} = 5G_{H_2O} - (G_{O_2\text{aqua}} + 4G_{H_3O^+}) = 5 * 0 - (329,68 + 4 * 22,44) = -419,44 \text{ kJ/mol}$ ; un sakrīt ar absolūto potenciālu skalu, Enerģijas saturs  $G_{O_2\text{gas}} = 303,1 \text{ kJ/mol}$  ūdenī palielinās uz  $G_{O_2\text{aqua}} = G_{O_2\text{gas}} + G_{O_2\text{sp}} = 303,1 + 26,58 = 329,68 \text{ kJ/mol}$ . Nernsta pus reakcijas ūdeņraža oksidēšanas  $4(Pt)H + 4H_2O = 4H_3O^+ + 4e^-$  standarta absolūtais potenciāls ir  $E^\circ_H = -0,27073 \text{ Volti}$ . Summā skābekļa reducēšanas reakcijā ar ūdeņradi sintezējas divas ūdens molekulas:

$$O_2\text{aqua} + 4(Pt)H \rightarrow 2H_2O \text{ ar absolūtās brīvās energijas eksoergisku izmaiņu } -523,925 \text{ kJ/mol :}$$

$$\Delta G_{eq} = (E^\circ_H - E^\circ_{O_2}) \cdot F \cdot 1 \cdot 4 = (-0,27073 - 1,0868) * 96485 * 4 / 1000 = -2 * 261,96 = -523,925 \text{ kJ/mol.}$$

Izmaiņa  $\Delta G_{eq2H_2O} = 2G_{H_2O} - 4G_{(Pt)H} - G_{O_2\text{aqua}} = 2 * 0 - (4 * G_{(Pt)H} + 329,68) = -523,925 \text{ kJ/mol}$  dod metāla ūdeņraža brīvās energijas saturu  $G_{H(Pt)} = (2G_{H_2O} - \Delta G_{eq2H_2O} - G_{O_2\text{aqua}}) / 4 = (2 * 0 + 523,925 - 329,68) / 4 = 194,23355 / 4 = 48,56 \text{ kJ/mol}$ .

Ūdeņraža elektroda atskaites punkta  $E^\circ_H = -0,27073 \text{ V}$  noteikšana **absolūtā** potenciāla un **absolūtās** brīvās energijas skalā Nernsta pus reakcijā pamatojas **inversās simetrijas** īpašībā: Inversās reakcijas potenciāls un brīvās energijas izmaiņa pieder vienam un tam pašam skaitlim ar pretēju zīmi abās absolūtās skalās.

**Absolūtās** un **inversās** brīvās energijas un potenciāla mēroga noteikšanai nepieciešama ūdens un hidroksonija uzskaitē, kuras pamatā ir Albertija dati par ūdeņraža gāzi un šķīduma absolūtās brīvās energijas vērtību. [8]

Nernsta pus reakcijā  $H(Pt) + H_2O = H_3O^+ + e^-$  standarta absolūtais potenciāls ir  $E^\circ_H = -0,27073 \text{ V}$ .

Ūdeņraža standarta oksidēšana **absolūtajā** potenciālu skalā producētā brīvās energijas izmaiņa ir eksoergīska:  $\Delta G_{eq} = E^\circ_H \cdot F \cdot 1 \cdot 1 = -0,27073 * 96485 * 1 = -26,12 \text{ kJ/mol}$  un ir identiska Hesa likumā aprēķinātās absolūtās brīvās energijas izmaiņai skalā, kas attiecināta uz ūdens brīvās energijas nulles saturu  $G_{H_2O} = 0 \text{ kJ/mol}$ :

$$\Delta G_{Hess\_eq} = G_{H_3O^+} + G_e - (G_{H(Pt)} + G_{H_2O}) = 22,44 + 0 - (48,56 + 0) = -26,12 \text{ kJ/mol}.$$

**Absolūtais** standarta potenciāls  $E^\circ_H = -0,27073 \text{ Voltos}$  sakrīt ar Albertija datiem absolūtai brīvai energijai. [8,15]

## Karbo anhidrāzes CA sintēze nepieciešams aktīvas biosfēras atraktors.

Karboanhidrāzes reaktivitāte un radītā fizioloģiskā bufera šķīduma protolīzes līdzsvara-atraktora vērtība pH=7,36 ir pašorganizējošais biosfēras atraktors. Reakcijas  $\text{CO}_2 + 2\text{H}_2\text{O} \rightarrow \text{H}_3\text{O}^+ + \text{HCO}_3^-$  akumulē brīvo enerģiju  $G_{\text{H}_3\text{O}^+ + \text{HCO}_3^-} = 18,38 + 60,14 = 78,52 \text{ kJ}$ , kas nepieciešama ķermeņa funkcionālai darbībai, tas ir bikarbonāta bufera sistēma ideālai reakciju secībai neatgriezeniskas homeostāzes kompleksajos procesos.

$\text{CO}_2$  nereagē ar ūdeni  $\text{H}_2\text{O}$  bez CA klātbūtnes.  $\text{CO}_2$  ir mazšķistošs un lēni reagē ar  $\text{OH}^-$ .

CA protolītiskā reaktivitāte rada funkcionālu aktīvu bikarbonātu bufera pašorganizēšanas atraktoru pH=7,36 ar ģenerētiem koncentrācijas gradientiem transportam  $\text{H}_3\text{O}^+$ ,  $\text{HCO}_3^-$ ,  $\text{CO}_{\text{aqua}}$  un  $\text{O}_2\text{aqua}$ ,  $\text{H}_2\text{O}$  osmozei cauri akvaporīnu kanāliem. CA liela ātruma protolīzē reagē  $\text{CO}_{\text{aqua}}$  ar divām ūdens molekulām:

## **Abstrakts.**

Uz Alberti bāzēts absolūtās brīvās energijas saturs  $G_{\text{H}_2\text{gas}}=85.6 \text{ kJ/mol}$  gāzei,  $G_{\text{H}_2\text{aqua}}=103 \text{ kJ/mol}$  ūdenim un  $G_{\text{H}_2\text{O}}=48,56 \text{ kJ/mol}$  metālam ūdeņradim pie nulles atskaites  $G_{\text{CO}_2\text{gas}}=0 \text{ kJ/mol}$  fona energijas ūdenim un oglekļa dioksīda  $\text{CO}_2$  gāzei. [8,15] Metāla ūdeņraža nulles klasiskā standarta potenciāla atskaitē tiek izmantota tā hidroksonija katjona  $[\text{H}_3\text{O}^+]=1.01 \text{ M}$  koncentrācija sērskābes  $[\text{H}_2\text{SO}_4]=1 \text{ M}$  šķīdumā ar blīvumu  $1.061 \text{ g/mL}$ .

Kopš 1920. gada Nernsta Nobela prēmijas ķīmijā saņemšanas visas elektroķīmijas sērijas reducētāju oksidēšanas pus reakciju standarta potenciāli ir noteikti attiecībā pret ūdeņraža metāla pus reakcijas klasisko standarta potenciālu  $E^\circ_{\text{H}}$  nulle. [1,15] Skābekļa, oglekļa dioksīda un ūdens protolīzes funkcionālās aktivitātes kvantitatīvie pētījumi atklāj ģenerētus daudzveidīgus Dzīvības pašorganizējošus atraktorus: ūdens  $[\text{H}_2\text{O}]=55.3 \text{ mol/Litrā}$  koncentrāciju,  $\text{pH}=7,36$ , enzīma karbo anhidrāzes (CA) reaktivitāte, gaisa skābekļa līmenis 20,95 %, osmolārā koncentrācija  $0,305 \text{ M}$ , jonu spēks  $0,25 \text{ M}$ , temperatūra  $310,15 \text{ K}$  grādi utt. . [1,15]

Liela ātruma protolīze ūdenī padara skābekli ugunsdrošu, CA funkcionāli aktivizē oglekļa dioksīdu, reaģējot ar divām ūdens molekulām, veidojot  $\text{H}_3\text{O}^++\text{HCO}_3^-$  koncentrācijas gradientus abpus membrānei osmozei pretēji koncentrācijas gradientiem bet protonu un bikarbonāta jonu transportēšanai lejup cauri protonu un bikarbonātu jonu kanāliem.

Iepriekšējās publikācijas atklāj neaizstājamu ūdens un hidroksonija uzskaiti līdzsvara reakciju termodinamiskajās izpausmēs, ieskaitot protolīzi un elektroķīmijas Nernsta pus reakcijas. [8,14,15] Pētījumi sasniedz metāla ūdeņraža termodinamiskā standarta potenciāla atsauces vērtību  $0.10166 \text{ Volti}$ . Alberty vārdā sniegtie dati par ūdeņraža brīvo enerģiju  $G_{\text{H}_2\text{gas}}=85.6 \text{ kJ/mol}$ ,  $G_{\text{H}_2\text{aqua}}=103 \text{ kJ/mol}$  ir atklājies **absolūtais** standarta **potenciāls**  $E^\circ_{\text{H}}=-0.27073 \text{ Volts}$  kā elektroda termodinamiskā atskaites vērtība ar absolūtās brīvās energijas izmaiņas vērtību  $\Delta G_{\text{eq}}=-26,12 \text{ kJ/mol}$ .
